
NOTICE TO READERS

A note from the Editor

Ana Herceg, Acting Editor, CDI

This is the last issue of *Communicable Diseases Intelligence (CDI)* for 1996. The editorial team of *CDI* would like to wish all our readers a very happy Christmas and best wishes for 1997. We would particularly like to thank all those readers who have contributed articles, editorials, correspondence, outbreak reports and surveillance reports to *CDI*.

The first issue of *CDI* for 1997 will be published on 9 January. You will notice that the publication day of *CDI* is changing from Monday to Thursday in 1997, in order to accommodate printing schedules. *CDI* will continue to be published every fortnight except for the fortnight of Christmas/New Year.

Finally, *CDI* will have a new cover and content design in 1997. As always, we would appreciate your comments on *CDI* in 1997.

OVERSEAS BRIEFS

Source: World Health Organization (WHO)

Yellow Fever, Ghana

A total of 27 cases of yellow fever with five deaths has been reported over a period of a few weeks in the Upper East Region of the country. Out of 15 blood samples tested, three were positive for yellow fever. Health authorities

have initiated a vaccination campaign of the population considered to be at risk. Some stocks of vaccine are already available and WHO is sending further supplies.

COMMUNICABLE DISEASES SURVEILLANCE

National Notifiable Diseases Surveillance System

The NNDSS is conducted under the auspices of the Communicable Diseases Network Australia New Zealand. The system coordinates the national surveillance of more than 40 communicable diseases or disease groups endorsed by the National Health and Medical Research Council (NHMRC). Notifications of these diseases are made to State and Territory health authorities under the provisions of their respective public health legislations. De-identified core unit data are supplied fortnightly for collation, analysis and dissemination. For further information, see CDI 1996;20:9-10.

Reporting period 10 to 23 November 1996

There were 2,522 notifications received for this two-week period (Tables 1, 2 and 3). The numbers of reports for

selected diseases have been compared with average data for this period in the previous three years (Figure 1).

Twenty-five notifications of measles were received in this period, 11 (44%) of which were for children under the age of 5 years. The number of cases remains low for the time of year (Figure 2).

Rubella was notified for 175 persons in this period. The number of notifications has risen in recent months but is below the level reported for the same period in the past two years (Figure 3). Eighty-four cases (48%) were for adults aged 15 to 24 years. There was a predominance of males, the male:female ratio being 2:1.

There were 324 cases of pertussis reported this period of which 60% were under the age of 20 years. Included were 137 notifications from Victoria where there is currently an outbreak.

Table 3. Notifications of rare¹ diseases received by State and Territory health authorities in the period 10 to 23 November 1996

DISEASE ²	Total this period	Reporting States or Territories	Year to date 1996
Brucellosis	3	Qld	35
Chancroid	0		1
Cholera	0		4
Hydatid infection	1	Qld	35
Leprosy	0		9

1. Fewer than 60 cases of each of these diseases were notified each year during the period 1988 to 1995.
2. No notifications have been received during 1996 for the following rare diseases: botulism; lymphogranuloma venereum; plague; rabies; yellow fever; or other viral haemorrhagic fevers.

Figure 1. Selected National Notifiable Diseases Surveillance System reports, and historical data¹

1. The historical data are the averages of the number of notifications in 9 previous 2-week reporting periods: the corresponding periods of the last 3 years and the periods immediately preceding and following those.

Figure 2. Measles notifications, 1991 to 1996, by month of onset

Figure 3. Rubella notifications, 1994 to 1996, by month of onset

Forty-eight notifications of Ross River virus were received in this period. Included were several apparent clusters in the Statistical Divisions of Fitzroy, Queensland (8 cases); Brisbane, Queensland (7 cases); Wide Bay-Burnett, Queensland (4 cases); Far North Queensland (4 cases); and Northern New South Wales (3 cases). Numbers remain low which is usual for the time of year.

One hundred and twenty-nine cases of gonococcal infection were reported in this period. Sixty-four (50%) were for persons in the 15 to 24 years age group. The male: female ratio was 1.7:1. Twenty cases were reported from the Statistical Division of Far North Queensland, 33 from the Northern Territory, 14 from Sydney and 15 from Kimberley, Western Australia.

Legionellosis was notified for 10 persons in this period. All cases were in the 40 to 84 years age range. For the year to date a total of 165 notifications have been received, of which 81% were for persons over 50 years of age (Figure 4). Most reports (69%) were for males.

Fifteen cases of meningococcal disease were reported in this period, of which 9 (60%) were for children 2 years of age or under. The number of notifications has remained stable since August, after peaking in July (Figure 5).

HIV and AIDS Surveillance

National surveillance for HIV disease is coordinated by the National Centre in HIV Epidemiology and Clinical Research (NCHECR), in collaboration with State and Territory health authorities and the Commonwealth of Australia. Cases of HIV infection are notified to the National HIV Database on the first occasion of diagnosis in Australia, by either the diagnosing laboratory (ACT, New South Wales, Tasmania, Victoria) or by a combination of laboratory and doctor sources (Northern Territory, Queensland, South Australia, Western Australia). Cases of AIDS are notified through the State and Territory health authorities to the National AIDS Registry. Diagnoses of both HIV infection and AIDS are notified with the person's date of birth and name code, to minimise duplicate notifications while maintaining confidentiality.

Tabulations of diagnoses of HIV infection and AIDS are based on data available three months after the end of the reporting interval indicated, to allow for reporting delay and to incorporate newly available information. More detailed information on diagnoses of HIV infection and AIDS is published in the quarterly Australian HIV Surveillance Report, available from the National Centre in HIV Epidemiology and Clinical Research, 376 Victoria Street, Darlinghurst NSW 2010. Telephone: (02) 332 4648 Facsimile: (02) 332 1837.

HIV and AIDS diagnoses and deaths following AIDS reported for July 1996, as reported to 31 October 1996, are included in this issue of CDI (Tables 4 and 5).

Australian Sentinel Practice Research Network

The Australian Sentinel Practice Research Network (ASPREN) comprises 99 sentinel general practitioners from throughout the country. Approximately 9,000 consultations are recorded each week for 12 conditions. Of these, CDI reports the consultation rate for influenza, rubella, measles, chickenpox, pertussis and gastroenteritis. For further information including case definitions see CDI 1996;20:98-99.

Data for weeks 46 and 47 ending 17 November and 24 November 1996 respectively are included in this issue of CDI (Table 6). There has been no significant change in the rates of notifications of gastroenteritis over recent reporting periods. Consultation rates for chickenpox rose during week 47 compared with recent weeks, while

those for influenza-like illnesses have remained steady. The numbers of cases of pertussis and measles have remained low.

Table 6. Australian Sentinel Practice Research Network reports, weeks 46 and 47, 1996

Condition	Week 46, to 17 November 1996		Week 47, to 24 November 1996

Sentinel chicken flocks are used to monitor flavivirus activity in Australia. The main viruses of concern are Murray Valley encephalitis (MVE) and Kunjin which cause the potentially fatal disease Australian encephalitis in humans. Currently 23 flocks are maintained in the north of Western Australia, 8 in the Northern Territory and 10 in Victoria. The flocks in Western Australia and the Northern Territory are tested all year round but those in Victoria are tested only from November to March, during the main MVE risk season.

Results are coordinated by the Arbovirus Laboratory in Perth and reported bimonthly.

Sentinel chicken serology was carried out for 16 of the 22 flocks in Western Australia in September and October 1996. There were no seroconversions during this period. Twenty-one of the 22 flocks of sentinel chickens were replaced during September. Those at Port Hedland were not replaced. New flocks were established at Lombadine, an Aboriginal community in the West Kimberley, and at Nullagine in the Pilbara. There are now 23 flocks in the north of Western Australia.

Five flocks of sentinel chickens from the Northern Territory were also tested in September and October. During this period there were no seroconversions to flaviviruses.

Gonococcal surveillance

John Tapsall, The Prince of Wales Hospital, High Street, Randwick, NSW, 2031 for the Australian Gonococcal Surveillance Programme

The Australian Gonococcal Surveillance Programme (AGSP) reference laboratories in the various States and Territories report data on sensitivity to an agreed 'core' group of antimicrobial agents quarterly. The antibiotics which are currently routinely surveyed are the penicillins, ceftriaxone, ciprofloxacin and spectinomycin, all of which are administered as single dose regimens. When *in vitro* resistance to a recommended agent is demonstrated in 5% or more of isolates, it is usual to reconsider the inclusion of that agent in current treatment schedules. Additional data are also provided on other antibiotics from time to time. At present all laboratories also test isolates for the presence of high level resistance to the tetracyclines. Tetracyclines are however not a recommended therapy for gonorrhoea. Comparability of data is achieved by means of a standardised system of testing and a programme-specific quality assurance process. Because of the substantial geographic differences in susceptibility patterns in Australia, regional as well as aggregated data are presented.

Reporting period 1 April to 30 June 1996

The AGSP laboratories examined 710 isolates of *Neisseria gonorrhoeae* for sensitivity to the penicillins, ceftriaxone, quinolones and spectinomycin and for high level resistance to the tetracyclines in the June quarter of 1996.

Penicillins

The usefulness of this group of antibiotics (penicillin, ampicillin, amoxycillin) is progressively diminishing and is least effective in Sydney and Melbourne where about a quarter of all isolates are resistant by one or more mechanisms. Figure 6 shows the proportion of isolates fully sensitive, less sensitive or relatively resistant to the penicillins by chromosomal mechanisms and the proportion of penicillinase-producing gonococci (PPNG) in different regions and as aggregated data for Australia. PPNG and relatively resistant isolates usually fail to respond to therapy with the penicillins. Those in the fully sensitive and less sensitive categories (minimal inhibitory concentration - MIC \leq 0.5 mg/L) usually respond to a regimen of standard treatment with the above penicillins.

There were 37 PPNG identified in this reporting period (5.2% of all isolates). These were found in all centres except Adelaide, with 14 PPNG reported from Sydney, 8 from Melbourne, 7 from Perth, 5 from the Northern Territory and lower numbers in the other centres. Infections with PPNG were acquired locally, and in Indonesia, the Philippines, Malaysia, Vietnam, China and Thailand. Fifty (7%) of all isolates were resistant to the penicillins by separate chromosomal mechanisms. These so-called CMRNG were present in all centres except Perth, but most prominent in Sydney (18 isolates, 13% of the total there) and Melbourne (23 isolates, 21%). Perhaps somewhat paradoxically, the

Figure 6. Penicillin resistance of gonococcal isolates for Australia and by region, 1 April to 30 June 1996

- FS Fully sensitive to penicillin, MIC \leq 0.03mg/L.
- LS Less sensitive to penicillin, MIC 0.06 - 0.5 mg/L.
- RR Relatively resistant to penicillin, MIC \geq 1 mg/L.
- PPNG Penicillinase producing *Neisseria gonorrhoea*.

proportion of isolates fully sensitive to penicillin increased in Sydney and Melbourne in this quarter.

Ceftriaxone and spectinomycin.

All isolates from all parts of Australia were sensitive to these injectable agents.

Quinolone antibiotics

Twenty-four isolates (3.4%) had altered resistance to this group of antibiotics (ciprofloxacin, norfloxacin and enoxacin), with half of these showing high level resistance (QRNG). High level resistance to the quinolones was present in strains from all centres. Nine QRNG (8.2%) were detected in Melbourne, 6 in Sydney (4.4%), 3 each in Darwin and Perth, 2 in Adelaide and one in Brisbane. Most infections with QRNG were acquired overseas, with China and the Philippines identified most often as countries of acquisition. Other sources of QRNG included Malaysia, Indonesia, Vietnam and Thailand.

High level tetracycline resistance

Thirty-four tetracycline-resistant *Neisseria gonorrhoea* (TRNG) were detected throughout Australia with isolates of this type again present in all centres. The highest proportion of TRNG was found in Sydney where the 11 TRNG represented 8.1% of all isolates. TRNG were also prominent in Perth (12 isolates, 6.6%) and there were 4 TRNG isolated in both Melbourne and Darwin. Overseas sources of TRNG most often identified were Vietnam and Indonesia. Local acquisition was also recorded.

Serious Adverse Events Following Vaccination Surveillance Scheme

The Serious Adverse Events Following Vaccination Surveillance Scheme is a national surveillance scheme which monitors the serious adverse events that occur rarely following vaccination. More details of the scheme were published in CDI 1995:19; 273-274.

Acceptance of a report does not imply a causal relationship between administration of the vaccine and the medical outcome, or that the report has been verified as to the accuracy of its contents.

It is estimated that 250,000 doses of vaccines are administered every month to Australian children under the age of six years.

Results for the reporting period 15 September to 23 November 1996

There were 14 reports of serious adverse events following vaccination for this reporting period. Reports were received from the Australian Capital Territory (1), the Northern Territory (3), South Australia (2), Tasmania (1), Victoria (3) and Western Australia (4).

The 14 reports included cases of persistent screaming, hypotonic/hyporesponsive episodes, convulsions and 4 'other' events (Table 7). The 'other' events included a severe local reaction and three episodes of acute urticarial rash, one with facial swelling.

Two children were hospitalised. All cases recovered.

LabWISE

The Virology and Serology Reporting Scheme, LabWISE, is a sentinel reporting scheme. Twenty-one laboratories contribute data on the laboratory identification of viruses and other organisms. Data are collated and published in Communicable Diseases Intelligence each fortnight. These data should be interpreted with caution as the number and type of reports received is subject to a number of biases. For further information, see CDI 1996;20:9-12.

There were 800 reports received in the CDI Virology and Serology Reporting Scheme in this period (Tables 8 and 9).

Laboratory reports of parvovirus for October are the highest recorded (Figure 7). The virus is presumed to be transmitted via respiratory secretions. Infection is most common in school aged children but can occur at any age. In the last fortnight, 26 reports were received, with diagnosis by IgM detection (25) and four-fold rise in titre (1).

There were 31 reports of influenza A for this reporting period. Diagnosis was by single high titre (28) and four-fold rise in titre (3).

There were 101 laboratory reports of *Bordetella pertussis* received in this fortnight, all but one were from Victoria. The increase in reports has been associated with an outbreak of pertussis in Victoria and may also reflect increased testing.

Table 7. Adverse events following vaccination for the period 15 September to 23 November 1996

Event	Vaccines					Reporting States or Territories	Total reports for this period
	DTP	DTP/Hib	DTP/OPV/Hib	DTP/OPV	MMR

Figure 7. Parvovirus laboratory reports, 1993 to 1996, by month of specimen collection

Figure 8. Mycoplasma pneumoniae laboratory reports, 1992 to 1996, by month of specimen collection

In the last fortnight, 52 reports of *Mycoplasma pneumoniae* were received, with diagnosis by IgM detection (38), single high titre (13) and four-fold rise in titre (1). The highest attack rates are generally in persons aged 5 to 20 years, but *Mycoplasma pneumoniae* can occur at any age and may

cause particularly severe disease in neonates. Reports appear to have peaked in September and are now expected to decline (Figure 8).

1. State or Territory of postcode, if reported, otherwise State or Territory of reporting laboratory.

2. The historical data are the averages of the numbers of reports in 6 previous 2 week reporting periods: the corresponding periods of the last 2 years and the periods immediately preceding and following those.

Table 9. Virology and serology laboratory reports by contributing laboratories for the reporting period 14 to 27 November 1996

STATE OR TERRITORY	LABORATORY	REPORTS
New South Wales	Institute of Clinical Pathology & Medical Research, Westmead	16
	Royal Alexandra Hospital for Children, Camperdown	8
	Royal Prince Alfred Hospital, Camperdown	11
Queensland	Queensland Medical Laboratory, West End	482
	State Health Laboratory, Brisbane	67
Tasmania	Northern Tasmanian Pathology Service, Launceston	3
	Royal Hobart Hospital, Hobart	9
Victoria	Microbiological Diagnostic Unit, University of Melbourne	9
	Royal Children's Hospital, Melbourne	122
	Victorian Infectious Diseases Reference Laboratory, Fairfield Hospital	73
